11/12/73 RIGHT CAROTID ANGIOGRAM: The bifurcation of the right common carotid artery in the neck is not seen.

Intracranially, there is visualization of the anterior middle cerebral and anterior choroidal arteries on the right side. There is flash filling of the posterior cerebral artery on this side. During the AP projection, contralateral compression in the neck was performed with visualization of the anterior and faint specification of the middle cerebral artery and posterior cerebral artery on the left side. An aneurysm is seen arising from the internal carotid artery at its point of bifurcation; and the aneurysm is directed superiorly. There doesn't

appear to be associated space or intracerebral hematoma in the neighbor of the aneurysm. Bulbous dilatation of the origin of the anterior middle artery is noted. The arteries are otherwise normal in their course and configuration. The venous phase shows the internal cerebral vein to be in the midline. The subependymal veins indicate normal size ventricles.

DEPRESSION: Right carotid angiogram demonstrating an aneurysm arising from the supraclinoid portion of the internal carotid artery. There is a small dilatation aneurysmal-like of the origin of the anterior choroidal artery as well.

CONSULTANT'S FINDINGS (HISTORY AND PHYSICAL)

FICU 206

19 yr old ♀ underwent chrysotherapy @ internal carotid aneurysm - pt. presented to the hospital w/ chrysotherapy of a 2nd carotid aneurysm at the supraclinoid portion.

It was well until 10/15/73 when she was heard to be screaming & was unresponsive 1 day later. She then passed out completely of severe headache & stupor. Several days later I.P. passed out in the chair. An angiogram demonstrated aneurysm PC papilloedema.

OPINION AND RECOMMENDATIONS:

@ s/p aneurysm repair on @ internal carotid @ I.P. about 10/15/73
